# TextArea Search

You need to implement simple search functionality for a *textarea* like the one in the browser (Ctrl/Cmd+F). The search must be case-sensitive and highlight all the matches for the search string in the input field.

You need to support the following cases:

- editor content scroll
- editor resize event
- text changing triggered by the user

It's forbidden to use any third-party libraries for this task (only standard library). Design is not important and will not be assessed. As an answer, you need to send a link to the public Git repository with the result. The repository must have a clear description of how to build and run your project. There also must be documentation and tests.
